Relaxed final-boundary comparison

All three methods use the same gain and threefold initial error. The panels compare anchor and fixed-clock errors, individual cycle durations, and first-cycle dwells. Blue denotes `daniel`, green `daniel-relaxed`, and orange `marcolino`.

The first 25 cycles show error convergence, conditioning activity, and requested versus applied minimum dwells. The two Daniel policies share a beta axis; Marcolino uses a separate delayed-switch count. All applied dwells meet the 3 μs bound.

Exact state trajectories over the same 3.432 ms window compare all three methods with the dashed fixed-clock reference. The panels show the state-space paths, both capacitor voltages, and inductor current; each method retains its own sampling times.
